

ECE 8101: Nonconvex Optimization for Machine Learning

Lecture Note 3-1: Federated Learning (feat. Distributed Learning)

Jia (Kevin) Liu

Assistant Professor
Department of Electrical and Computer Engineering
The Ohio State University, Columbus, OH, USA

Spring 2022

Outline

In this lecture:

- Key Idea of Distributed Optimization for Federated Learning
- Representative Algorithms
- Convergence Results

Revisit the General Expectation Minimization Problem

$$\min_{\mathbf{x} \in \mathbb{R}^d} f(\mathbf{x}) = \min_{\mathbf{x} \in \mathbb{R}^d} \mathbb{E}_{\xi \sim \mathcal{D}}[f(\mathbf{x}, \xi)]$$

- The SGD method using mini-batch \mathcal{B}_k with $|\mathcal{B}_k| = B_k$ is:

$$\mathbf{x}_{k+1} = \mathbf{x}_k - \frac{s_k}{B_k} \sum_{i=1}^{B_k} \nabla f(\mathbf{x}_k, \xi_i)$$

- Key Insight:** The “summation” in the mini-batched version of SGD implies a **decomposable** structure that lends itself to **distributed** implementation!
 - Each stochastic gradient $\nabla f(\mathbf{x}_k, \xi_i)$ can be computed by a “worker” i
 - B_k workers can compute such stochastic gradients **in parallel**
 - A server collects the stochastic gradients returned by workers and **aggregate**

This insight is the foundation of Distributed Learning and Federated Learning

Distributed Learning in Data Center Setting

- Distributed ML Systems

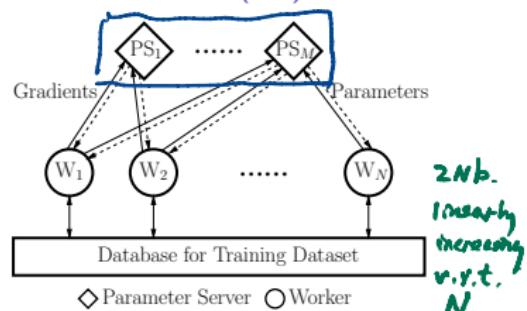

- Time consuming
- Resource intensive

Model	ImageClassification	DeepSpeech2
Dataset	ResNet50	LibriSpeech
System	8 GPUs	16 GPUs
Time	115 minutes ^[1]	3-5 days ^[2]

Federated Learning System Architecture

Federated Learning (FL)

- The term “federated learning” was first coined in 2016 (arXiv):
 - ▶ “We term our approach *Federated Learning*, since the learning task is solved by a loose federation of participating devices (which we refer to as *clients*) which are coordinated by a central server.” [McMahan et al. AISTATS’17]
- Key motivations of FL:
 - ▶ FL was first focused on **mobile** & **edge** devices collaborating to train a **global model** and later became a general learning paradigm
 - ▶ No need to transfer clients' data to the server to preserve **privacy**
- A very active ongoing research field with the following defining challenges:
 - ▶ Dataset sizes are **unbalanced** across clients in general
 - ▶ Datasets are **non-i.i.d.** across clients in general
 - ▶ Could involve a **massive** number of client devices
 - ▶ **Limited communication** bandwidth between server and clients
 - ▶ Limited device **availability** (e.g., powered-off, charging, no wifi...)
- Two widely studied FL settings:
 - ▶ Cross-device: Huge number of (unreliable) clients (e.g., mobile devices)
 - ▶ Cross-silo: Small number of (relatively) reliable clients (hospitals, banks, etc.)

Cross-Device Federated Learning

According to [Kairouz et al. arXiv-1912.04977]: *59 authors.*

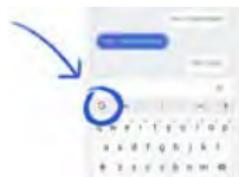

- Total population: 10^6 – 10^{10} devices
- Device selected per-round: 50–5000
- Total devices participated in training a model: 10^5 – 10^7
- Number of rounds for convergence: 500–10000
- Wall-clock training time: 1–10 days
- Data partition: By samples

Cross-Silo Federated Learning

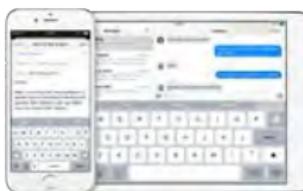

- The number of clients is relatively small. Often reasonable to assume that clients are **available at all times**
- Relevant when a number of companies or organizations **share incentive** to training a model based on their data, but cannot share data directly
- **Data partition:** Could be either by samples or by features
 - ▶ Also referred to as “horizontal” and “vertical” FL in the literature, respectively
 - ▶ **By examples:** Relevant in cross-silo FL when a single organization cannot centralize their data
 - ▶ **By features:** Relevant in cross-silo FL if data security/privacy is of higher concerns (e.g., banks)
- **Challenges:**
 - ▶ Incentive mechanisms: participants might be competitors; utility fairness among clients (free-rider problem); dividing earning among participants, etc.
 - ▶ Preserving privacy on different levels (clients, users, etc.)

Applications of Federated Learning

- Cross-device FL:

Google Gboard

Apple QuickType

Apple "Hey Siri"

- ▶ **Google:** Extensive use of cross-device FL in Gboard mobile keyboard, features on Pixel phones, and Android Messages
- ▶ **Apple:** Use of cross-device FL in QuickType keyboard next word prediction and vocal classifier for "Hey Siri"
- ▶ doc.ai uses cross-device FL for medical research, Snips uses cross-device FL for hotword detection, etc.

- Cross-silo FL:

- ▶ Financial risk prediction for reinsurance, pharmaceutical discovery, electronic health record mining, medical data segmentation, smart manufacturing, etc.

Typical Federated Training Process

- Client selection:
 - ▶ Server samples from a set of available clients (idle, on wi-fi, plugged in...)
- Broadcast:
 - ▶ The selected clients download the current model weights
- Client computation:
 - ▶ Each selected client locally computes an update to the model by some algorithm (e.g., SGD or variants) on the local data
 - ▶ Potential additional processing: Privacy, compression, etc.
- Aggregation:
 - ▶ Server collects an aggregates of the updates from clients
 - ▶ Potential additional processing: filtering for security, etc.
- Model update:
 - ▶ The server updates the global model based on aggregated updates
 - ▶ Potential additional processing: additional scaling, momentum, extra data, etc.

Why Does Federated Learning Generate So Much Interest?

- FL is inherently **inter-disciplinary**:
 - ▶ Machine learning
 - ▶ Distributed optimization techniques
 - ▶ Cryptography
 - ▶ Security
 - ▶ Differential privacy
 - ▶ Fairness
 - ▶ Compressed sensing
 - ▶ Crowd-sensing
 - ▶ Wireless networking
 - ▶ Economics
 - ▶ Statistics
 - ▶ May play a role in emerging technologies (Blockchains, Metaverse, ...)
- Many of the hardest problems in FL are at the intersections of multiple areas

Optimization Algorithms for Federated Learning

- Key differences between distributed optimization and FL:
 - ▶ Non-i.i.d. and unbalanced datasets across clients
 - ▶ Limited communication bandwidth
 - ▶ Unreliable and limited client device availability
- FedAvg Algorithm (aka Local SGD/parallel SGD): basic template of FL
 - ▶ N : Num. of clients; M : Clients per round;
 - ▶ T : Total communication round; K : Num. of local steps per round
 - ▶ At Server:

- ① Initialize $\bar{\mathbf{x}}_0$
- ② for each round $t = 1, 2, \dots, T$ do
 - $S_t \leftarrow$ (random set of M clients)
 - for each client $i \in S_t$ in parallel do
 - $\mathbf{x}_i^{t+1} \leftarrow \text{ClientUpdate}(i, \bar{\mathbf{x}}^t)$
 - $\bar{\mathbf{x}}^{t+1} \leftarrow (1/M) \sum_{i=1}^M \mathbf{x}_i^{t+1}$

[Yang-Fang-Lin, ICML'21]

"6-FedAvg-Two-Sided-LR"

- ▶ ClientUpdate(i, \mathbf{x}):

- ① $\mathbf{x}_0 \leftarrow \mathbf{x}$
- ② for local step $k = 0, \dots, K-1$ do
 - $\mathbf{x}_{k+1} \leftarrow \mathbf{x}_k - s_k \nabla f(\mathbf{x}_k, \xi)$ for $\xi \sim \mathcal{P}_i$
- ③ Return \mathbf{x}_K to server

of local comp.
* reduce comm. cost.

Transmit "update": $-s \sum_{i=1}^k g_{i,k}$

G-FedArg - Two-Sided - LR: (Yang-Fang-Liu, ICLR'21),

Client i: send $\Delta_i^t = -\sum_{k=0}^{K-1} g_{i,k}^t$

Server: i Receive $\Delta_i^t, \forall i \in S$

2° Let $\Delta^t = \frac{1}{|S|} \sum_{i \in S} \Delta_i^t$

$$3^{\circ} \bar{x}^{t+1} = \bar{x}^t + \underbrace{s}_{\text{w}} \Delta^t.$$

$$\bar{x}^{t+1} = \bar{x}^t + \underbrace{ss_L}_{\text{effective LR.}} (\dots)$$

Org FedArg,

Client i: $x_i^{t+1} = x_i^t - s_L \sum_{k=0}^{K-1} g_{i,k}^t$

Server: $\bar{x}^{t+1} = \frac{1}{|S|} \sum_{i \in S} x_i^{t+1}$

$$\begin{aligned} \bar{x}^{t+1} &= \frac{1}{|S|} \sum_{i \in S} x_i^{t+1} = \frac{1}{|S|} \sum_{i \in S} \left[x_i^t - s_L \sum_{k=0}^{K-1} g_{i,k}^t \right] \\ &= \frac{1}{|S|} \sum_{i \in S} x_i^t + \frac{1}{|S|} \sum_{i \in S} \left(s_L \sum_{k=0}^{K-1} (-g_{i,k}^t) \right) = \Delta_i^t \end{aligned}$$

$$= \bar{x}^t + \underbrace{\frac{1}{|S|} \sum_{i \in S} \Delta_i^t}_{\Delta^t}$$

$$= \bar{x}^t + \underbrace{|S|}_{\text{w}} \cdot \Delta^t \quad \text{special case of G-FedArg-TSLR w/ } s=1.$$

ss_L

Convergence Results: FedAvg with I.I.D. Datasets

- Mini-batch of data used for a client's local update is statistically identical to a uniform sampling (with replacement) from the union of all clients' datasets
- Although unlikely in practice, i.i.d. case provides basic understanding for FL
- For simplicity, assume for now $M = N$. Consider the problem:

$$\min_{\mathbf{x} \in \mathbb{R}^m} f(\mathbf{x}) \triangleq \min_{\mathbf{x} \in \mathbb{R}^m} \frac{1}{N} \sum_{i=1}^N f_i(\mathbf{x}),$$

where $f_i(\mathbf{x}) \triangleq \mathbb{E}_{\xi_i \sim \mathcal{D}_i} [F_i(\mathbf{x}, \xi_i)]$ is nonconvex

- Assumptions:

- ▶ L -smooth: $\|\nabla f_i(\mathbf{x}) - \nabla f_i(\mathbf{y})\| \leq L\|\mathbf{x} - \mathbf{y}\|$, $\forall \mathbf{x}, \mathbf{y}$.
- ▶ Bounded variance and second moments:
 $\mathbb{E}_{\xi_i \sim \mathcal{P}_i} [\|\nabla F_i(\mathbf{x}, \xi_i) - \nabla f_i(\mathbf{x})\|^2] \leq \sigma^2$, $\mathbb{E}_{\xi_i \in \mathbb{D}_i} [\|\nabla F_i(\mathbf{x}, \xi_i)\|^2] \leq G^2$, $\forall \mathbf{x}, i$
- ▶ Unbiased stochastic gradient: $\mathbf{G}_i^t = \nabla F_i(\mathbf{x}_i^{t-1}, \xi_i^t)$ with
 $\mathbb{E}_{\xi_i^t \sim \mathcal{D}_i} [\mathbf{G}_i^t | \boldsymbol{\xi}^{[t-1]}] = \nabla f_i(\mathbf{x}_i^{t-1})$, $\forall i$, where $\boldsymbol{\xi}^{[t-1]} \triangleq [\xi_i^\tau]_{i \in [N], \tau \in [t-1]}$

Convergence Results: FedAvg with I.I.D. Datasets

To fix notation, we use the following equivalent code for FedAvg (also referred to as Parallel Restarted SGD in [Yu et al. AAAI'19]):

- ① Initialize $\mathbf{x}_i^0 = \bar{\mathbf{y}} \in \mathbb{R}^m$. Choose constant step-size $s > 0$ and synchronization interval $K > 0$
- ② **for** $t = 1, \dots, T$ **do**
 - Each client i observes stochastic gradient \mathbf{G}_i^t of $f_i(\cdot)$ at \mathbf{x}_i^{t-1}
 - if** $t \bmod K = 0$ **then**
 - Compute node average $\bar{\mathbf{y}} \triangleq \frac{1}{N} \sum_{i=1}^N \mathbf{x}_i^{t-1}$
 - Each client i in parallel updates its local solution
 - $$\mathbf{x}_i^t = \bar{\mathbf{y}} - s\mathbf{G}_i^t, \quad \forall i$$
- else**
 - Each client i in parallel updates its local solution:
- $$\mathbf{x}_i^t = \mathbf{x}_i^{t-1} - s\mathbf{G}_i^t, \quad \forall i$$
- end if**
- end for**

Convergence Results: FedAvg with I.I.D. Datasets

Theorem 1 ([Yu et al. AAAI'19])

Under the stated assumptions and if $s \in (0, \frac{1}{L}]$, then for all $T \geq 1$, then the iterates $\{\bar{\mathbf{x}}_t\}$ generated by FedAvg satisfies:

$$\frac{1}{T} \sum_{t=1}^T \mathbb{E}[\|\nabla f(\bar{\mathbf{x}}^{t-1})\|^2] \leq \frac{2}{sT}(f(\bar{\mathbf{x}}^0) - f^*) + 4s^2 K^2 G^2 L^2 + \frac{L}{N}s\sigma^2,$$

$= O(\frac{1}{T})$

where f^* is the optimal value of the FL problem.

Convergence Results: FedAvg with I.I.D. Datasets

Corollary 2 ([Yu et al. AAAI'19])

- If we let $s = \frac{\sqrt{N}}{L\sqrt{T}}$:

$$\frac{1}{T} \sum_{t=1}^T \mathbb{E}[\|\nabla f(\bar{x}^{t-1})\|^2] \leq \frac{2L}{\sqrt{NT}}(f(\bar{x}^0) - f^*) + 4\frac{N}{T}K^2G^2 + \frac{1}{\sqrt{NT}}\sigma^2$$

$\simeq O\left(\frac{1}{\sqrt{NT}}\right)$ ← "linear speedup"

- If we further let $K \leq \frac{T^{1/4}}{N^{3/4}}$:

$$\frac{1}{T} \sum_{t=1}^T \mathbb{E}[\|\nabla f(\bar{x}^{t-1})\|^2] \leq \frac{2L}{\sqrt{NT}}(f(\bar{x}^0) - f^*) + \frac{4}{\sqrt{NT}}G^2 + \frac{1}{\sqrt{NT}}\sigma^2$$

$= O\left(\frac{1}{\sqrt{NT}}\right)$

For SGD: $\frac{1}{T} \sum_{t=1}^T \mathbb{E}[\|\nabla f(x^{t-1})\|^2] = \frac{C}{\sqrt{T}} \leq \varepsilon^2 \Rightarrow T \geq O\left(\frac{1}{\varepsilon^2}\right)$.

FedAvg: $\frac{1}{T} \sum_{t=1}^T \mathbb{E}[\|\nabla f(\bar{x}^{t-1})\|^2] = \frac{C'}{\sqrt{NT}} \leq \varepsilon^2 \Rightarrow T \geq O\left(\frac{1}{N\varepsilon^2}\right)$ ← linear speedup.

Theorem 1 ([Yu et al. AAAI'19])

Under the stated assumptions and if $s \in (0, \frac{1}{L}]$, then for all $T \geq 1$, then the iterates $\{\mathbf{x}_t\}$ generated by FedAvg satisfies:

$$\frac{1}{T} \sum_{t=1}^T \mathbb{E}[\|\nabla f(\bar{\mathbf{x}}^{t-1})\|^2] \leq \frac{2}{sT}(f(\bar{\mathbf{x}}^0) - f^*) + 4s^2 K^2 G^2 L^2 + \frac{L}{N} s \sigma^2,$$

$= O(\frac{1}{T})$

where f^* is the optimal value of the FL problem.

Proof. From L -smoothness and descent lemma:

$$\mathbb{E}[f(\bar{\mathbf{x}}^t)] \leq \mathbb{E}[f(\bar{\mathbf{x}}^{t-1})] + \mathbb{E}[\nabla f(\bar{\mathbf{x}}^{t-1})^T (\bar{\mathbf{x}}^t - \bar{\mathbf{x}}^{t-1})] + \frac{L}{2} \mathbb{E}[\|\bar{\mathbf{x}}^t - \bar{\mathbf{x}}^{t-1}\|^2] \quad (1)$$

We first bound the quadratic term:

$$\bar{\mathbf{x}}^t \triangleq \frac{1}{N} \sum_{i=1}^N \mathbf{x}_i^t = \frac{1}{N} \sum_{i=1}^N (\mathbf{x}_i^{t-1} - s \mathbf{g}_i^t) = \bar{\mathbf{x}}^{t-1} - \frac{1}{N} s \sum_{i=1}^N \mathbf{g}_i^t \quad (2).$$

$$\text{Therefore, } \mathbb{E}[\|\bar{\mathbf{x}}^t - \bar{\mathbf{x}}^{t-1}\|_2^2] = \mathbb{E}\left[\left\|s \frac{1}{N} \sum_{i=1}^N \mathbf{g}_i^t\right\|_2^2\right]$$

$$= s^2 \mathbb{E}\left[\left\|\frac{1}{N} \sum_{i=1}^N \mathbf{g}_i^t\right\|^2\right]$$

$$\begin{aligned} & \stackrel{\text{add & subtract mean of } \mathbf{G}}{=} s^2 \mathbb{E}\left[\left\|\frac{1}{N} \sum_{i=1}^N (\mathbf{g}_i^t - \nabla f_i(\mathbf{x}_i^{t-1}))\right\|^2\right] + s^2 \mathbb{E}\left[\left\|\frac{1}{N} \sum_{i=1}^N \nabla f_i(\mathbf{x}_i^{t-1})\right\|^2\right] \\ & \stackrel{\mathbb{E}[\|\mathbf{z}\|^2]}{=} \end{aligned}$$

$$\begin{aligned} & \stackrel{\mathbb{E}[\|\mathbf{z} - \mathbb{E}[\mathbf{z}]\|^2]}{=} \left(\mathbb{E}[\|\mathbf{z}_1 + \dots + \mathbf{z}_n\|^2] \leq \mathbb{E}[\|\mathbf{z}_1\|^2 + \dots + \|\mathbf{z}_n\|^2] = \sum_{i=1}^n \mathbb{E}[\|\mathbf{z}_i\|^2] \text{ for r.v. } \mathbf{z}_1, \dots, \mathbf{z}_n \text{ indep and o-mean.} \right) \\ & + \mathbb{E}[\mathbf{z}] \mathbb{E}[\mathbf{z}]^T \end{aligned}$$

$$= \frac{s^2}{N^2} \sum_{i=1}^N \mathbb{E}\left[\left\|\mathbf{g}_i^t - \nabla f_i(\mathbf{x}_i^{t-1})\right\|^2\right] + s^2 \mathbb{E}\left[\left\|\frac{1}{N} \sum_{i=1}^N \nabla f_i(\mathbf{x}_i^{t-1})\right\|^2\right]$$

$$\leq \frac{1}{N} s^2 \mathbb{E}\left[\left\|\frac{1}{N} \sum_{i=1}^N \nabla f_i(\mathbf{x}_i^{t-1})\right\|^2\right] \quad (3)$$

Now, for the cross term:

$$\mathbb{E}[\nabla f(\bar{x}^{t-1})^T (\bar{x}^t - \bar{x}^{t-1})] = -s \mathbb{E}\left[\nabla f(\bar{x}^{t-1})^T \cdot \frac{1}{N} \sum_{i=1}^N g_i^t\right]$$

Iter. law

$$\stackrel{(4) \text{ EIT}}{=} -s \mathbb{E}\left[\mathbb{E}\left[\nabla f(\bar{x}^{t-1})^T \cdot \frac{1}{N} \sum_{i=1}^N g_i^t \mid \xi^{t-1}\right]\right]$$

$$= -s \mathbb{E}\left[\nabla f(\bar{x}^{t-1})^T \cdot \frac{1}{N} \sum_{i=1}^N \mathbb{E}[g_i^t \mid \xi^{t-1}] \right] \quad \checkmark \text{ unbiasedness}$$

$$= -s \mathbb{E}\left[\underbrace{\nabla f(\bar{x}^{t-1})^T}_a \underbrace{\frac{1}{N} \sum_{i=1}^N \nabla f_i(\bar{x}_i^{t-1})}_b\right]$$

$$a^T b = \pm (\|a\|^2 + \|b\|^2 - \|a - b\|^2)$$

$$= -\frac{s}{2} \mathbb{E}\left[\|\nabla f(\bar{x}^{t-1})\|^2 + \left\|\frac{1}{N} \sum_{i=1}^N \nabla f_i(\bar{x}_i^{t-1})\right\|^2 - \left\|\nabla f(\bar{x}^{t-1}) - \frac{1}{N} \sum_{i=1}^N \nabla f_i(\bar{x}_i^{t-1})\right\|^2\right] \quad (4)$$

Plugging (3) and (4) into (1):

$$\mathbb{E}[f(\bar{x}^t)] \leq \mathbb{E}[f(\bar{x}^{t-1})] - \frac{s-s^2L}{2} \mathbb{E}\left[\left\|\frac{1}{N} \sum_{i=1}^N \nabla f_i(\bar{x}_i^{t-1})\right\|^2\right]$$

$$-\frac{s}{2} \mathbb{E}\left[\|\nabla f(\bar{x}^{t-1})\|^2\right] + \underbrace{\frac{s}{2} \mathbb{E}\left[\left\|\nabla f(\bar{x}^{t-1}) - \frac{1}{N} \sum_{i=1}^N \nabla f_i(\bar{x}_i^{t-1})\right\|^2\right]}_{(a)} + \frac{L^2 s^2}{2N} \quad (7)$$

$$(a) \stackrel{\text{def of }}{=} \mathbb{E}\left[\left\|\frac{1}{N} \sum_{i=1}^N \nabla f_i(\bar{x}_i^{t-1}) - \frac{1}{N} \sum_{i=1}^N \nabla f_i(\bar{x}_i^{t-1})\right\|^2\right]$$

$$= \frac{1}{N^2} \mathbb{E}\left[\left\|\sum_{i=1}^N (\nabla f_i(\bar{x}_i^{t-1}) - \nabla f(\bar{x}_i^{t-1}))\right\|^2\right]$$

$$\leq \frac{1}{N} \mathbb{E}\left[\sum_{i=1}^N \left\|\nabla f_i(\bar{x}_i^{t-1}) - \nabla f_i(\bar{x}_i^{t-1})\right\|^2\right] \leq L^2 \|\bar{x}^{t-1} - \bar{x}_i^{t-1}\|^2$$

$\mathbb{E}[\|z_1 + \dots + z_n\|^2]$
 $\leq n \mathbb{E}[\|z_1\|^2 + \dots + \|z_n\|^2]$
 for r.v. z_1, \dots, z_n
 not nec. indep.
 with $n=N$

$$\leq \frac{L^2}{N} \sum_{i=1}^N \underbrace{\mathbb{E} [\|\bar{x}^{t-1} - x_i^{t-1}\|^2]}_{\text{client drift.}}$$

Lemma 1: (Client Drift) - Under FedAvg, it holds that

$$\mathbb{E} [\|\bar{x}^t - x_i^t\|^2] \leq 4s^2 K^2 G^2.$$

$$\text{where } \bar{x}^t \triangleq \frac{1}{N} \sum_{i=1}^N x_i^t.$$

Proof. For $t > 1$ and $i \in [N]$. Note FedAvg calculates client average $\bar{y} \triangleq \frac{1}{N} \sum_{i=1}^N x_i^{t-1}$. Consider the largest $t_0 \leq t$ s.t. $\bar{y} = \bar{x}^{t_0}$ (t_0 is most recent global update).

From the updates in FedAvg:

$$x_i^t = \bar{y} - s \sum_{\tau=t_0+1}^t g_i^\tau \quad (5)$$

$$\begin{aligned} \text{Thus, } \bar{x}^t &\triangleq \frac{1}{N} \sum_{i=1}^N x_i^t = \frac{1}{N} \sum_{i=1}^N \left(\bar{y} - s \sum_{\tau=t_0+1}^t g_i^\tau \right) \\ &= \bar{y} - s \sum_{\tau=t_0+1}^t \frac{1}{N} \sum_{i=1}^N g_i^\tau \end{aligned} \quad (6)$$

Using (5) and (6), we have:

$$\begin{aligned} \mathbb{E} [\|\bar{x}^t - x_i^t\|^2] &= \mathbb{E} \left[\left\| s \sum_{\tau=t_0+1}^t \frac{1}{N} \sum_{i=1}^N g_i^\tau - s \sum_{\tau=t_0+1}^t g_i^\tau \right\|^2 \right] \\ &= s^2 \mathbb{E} \left[\left\| \underbrace{\sum_{\tau=t_0+1}^t \frac{1}{N} \sum_{i=1}^N g_i^\tau}_{\text{green bracket}} - \underbrace{\sum_{\tau=t_0+1}^t g_i^\tau}_{\text{green bracket}} \right\|^2 \right] \end{aligned}$$

$(*)$

$$\begin{cases} \mathbb{E} [\|z_1 + \dots + z_n\|^2] \\ \leq n \mathbb{E} [\|z_1\|^2 + \dots + \|z_n\|^2] \\ \text{for r.v. } z_1, \dots, z_n \\ \text{not necc. indep.} \\ \text{with } n=2. \end{cases}$$

$$\begin{aligned}
&\leq 2s^2 \mathbb{E} \left[\left\| \sum_{t=t_0+1}^T \frac{1}{N} \sum_{i=1}^N G_i^T \right\|^2 + \left\| \sum_{t=t_0+1}^T G_i^T \right\|^2 \right] \\
&\quad \text{switch} \quad \text{switch} \quad \left(\begin{array}{l} \text{using } (*) \\ w/ n = t - t_0 \end{array} \right) \\
&\leq 2s^2(t-t_0) \mathbb{E} \left[\sum_{t=t_0+1}^T \left\| \frac{1}{N} \sum_{i=1}^N G_i^T \right\|^2 + \sum_{t=t_0+1}^T \|G_i^T\|^2 \right] \\
&\stackrel{\text{use } (*)}{\leq} 2s^2(t-t_0) \mathbb{E} \left[\sum_{t=t_0+1}^T \left(\frac{1}{N} \sum_{i=1}^N \|G_i^T\|^2 \right) + \sum_{t=t_0+1}^T \|G_i^T\|^2 \right] \quad \left(\begin{array}{l} \text{use } (*) \\ w/ n = N \end{array} \right) \\
&\stackrel{\leq k}{\leq} \sum_{t=t_0+1}^T \sum_{i=1}^N \|G_i^T\|^2 \quad \stackrel{\leq G^2}{=} \sum_{t=t_0+1}^T \|G_i^T\|^2 \quad \stackrel{\leq k}{\leq} \sum_{t=t_0+1}^T \sum_{i=1}^N \|G_i^T\|^2 \quad \stackrel{\leq G^2}{=} \sum_{t=t_0+1}^T \|G_i^T\|^2 \\
&\leq 4s^2 k^2 G^2. \quad \blacksquare
\end{aligned}$$

(Continue the Proof of Thm 1):

With Lemma 1, (7) becomes:

$$\begin{aligned}
\mathbb{E}[f(\bar{x}^t)] &\leq \mathbb{E}[f(\bar{x}^{t-1})] - \frac{s-s^2L}{2} \mathbb{E}\left[\left\|\frac{1}{N} \sum_{i=1}^N \nabla f_i(\bar{x}^{t-1})\right\|^2\right] \\
&\quad - \frac{s}{2} \mathbb{E}\left[\|\nabla f(\bar{x}^{t-1})\|^2\right] + 2s^3 k^2 G^2 L^2 + \frac{L s^2 \sigma^2}{2N}. \quad (8)
\end{aligned}$$

Also, note that $0 < s \leq \frac{L}{2} \Rightarrow \frac{s}{2}(1-sL) \geq 0$. Then

$$(8) \leq \mathbb{E}[f(\bar{x}^{t-1})] - \frac{s}{2} \mathbb{E}\left[\|\nabla f(\bar{x}^{t-1})\|^2\right] + 2s^3 k^2 G^2 L^2 + \frac{L s^2 \sigma^2}{2N}.$$

Dividing both sides by $\frac{s}{2}$ and rearranging:

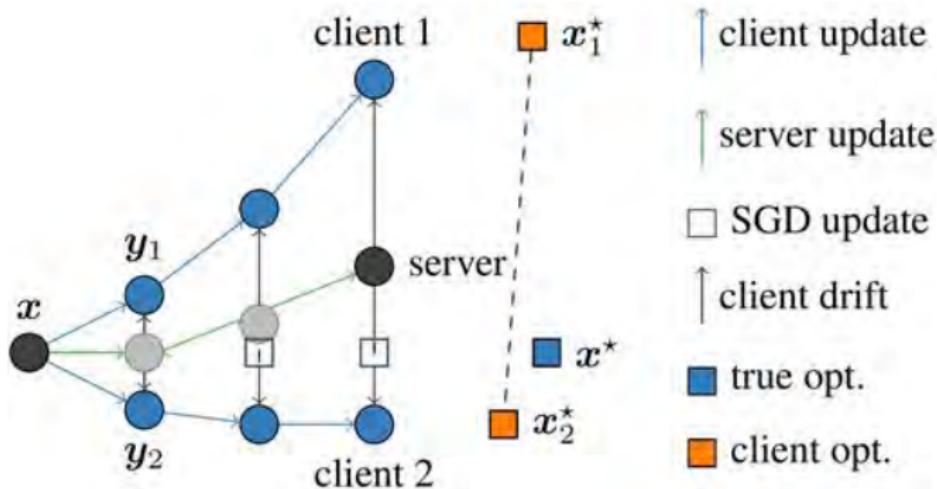

$$\mathbb{E}\left[\|\nabla f(\bar{x}^{t-1})\|^2\right] \leq \frac{2}{s} (\mathbb{E}[f(\bar{x}^{t-1})] - \mathbb{E}[f(\bar{x}^t)]) + 4s^2 k^2 G^2 L^2 + \frac{L s^2 \sigma^2}{2N}$$

Summing over $t \in [T]$, dividing both sides by T .

and using $\mathbb{E}[f(\bar{x}^T)] \geq f^*$, we complete the proof. \blacksquare

Federated Learning with Non-I.I.D. Datasets

- “Client drift” problem with non-i.i.d. datasets (figure from [Karimireddy et al. ICML’20])

- Impose a limit on the number of local updates in FL with non-i.i.d. datasets (different algorithmic designs in FL lead to different limits)

What Do You Mean Exactly by Saying "Non-I.I.D" in FL?

- Bounded difference between client and global gradients (e.g., [Yu et al. ICML 2019] or [Yang et al. ICLR'21]): *gradients*

$$\frac{1}{N} \sum_{i=1}^N \|\nabla f_i(\mathbf{x}) - \nabla f(\mathbf{x})\|^2 \leq \sigma_G^2 \quad \text{or} \quad \|\nabla f_i(\mathbf{x}) - \nabla f(\mathbf{x})\|^2 \leq \sigma_G^2$$

(Δ)

- A unified bounded gradient dissimilarity (G, B) -BGD model [Karimireddy et al. ICML'20]:

$$\frac{1}{N} \sum_{i=1}^N \|\nabla f_i(\mathbf{x})\|^2 \leq G^2 + B^2 \|\nabla f(\mathbf{x})\|^2$$

*1° if $B=0$.
2° if $G^2=0$.
bounded var.
of local grad.*

- Bounded difference between client and global optimal values (e.g., [Li et al., ICLR'20]):

$$f^* - \sum_{i=1}^N p_i f_i^* \triangleq \Gamma < \infty$$

Convergence Results: FedAvg with Non-I.I.D. Datasets

with bounded grad dissimilarity in Δ .

Theorem 3 ([Yu et al. ICML'19] Momentum-less Version)

Under the stated assumptions and if $s \in (0, \frac{1}{L}]$ and $K \leq \frac{1}{6Ls}$, then for all $T \geq 1$, then the iterates $\{\mathbf{x}_t\}$ generated by FedAvg satisfies:

$$\frac{1}{T} \sum_{t=0}^{T-1} \mathbb{E}[\|\nabla f(\bar{\mathbf{x}}^t)\|^2] \leq \underbrace{\frac{2}{sT}(f(\bar{\mathbf{x}}^0) - f^*)}_{O(\frac{1}{T})} + \underbrace{\frac{L}{N}s\sigma^2 + 4s^2KG^2L^2 + 9L^2s^2K^2\sigma_G^2}_{\text{const. error}},$$

where f^* is the optimal value of the FL problem.

Convergence Results: FedAvg with Non-I.I.D. Datasets

Corollary 4 ([Yu et al. ICML'19])

- If we let $s = \frac{\sqrt{N}}{\sqrt{T}}$ and $K = 1$, then for $T \geq 36L^2N$

$= O(\frac{1}{\sqrt{NT}})$: "linear speedup".

$$\frac{1}{T} \sum_{t=0}^{T-1} \mathbb{E}[\|\nabla f(\bar{\mathbf{x}}^t)\|^2] = O\left(\frac{1}{\sqrt{NT}}\right) + O\left(\frac{N}{T}\right)$$

- If we let $s = \frac{\sqrt{N}}{\sqrt{T}}$ and let $\underline{K} = O(\frac{T^{1/4}}{N^{3/4}})$, then for $T \geq L^2N$:

"T": rounds $K = O(\frac{T^{\frac{1}{4}}}{N})$.

In G-FedAvg-TSLR

$$\frac{1}{T} \sum_{t=0}^{T-1} \mathbb{E}[\|\nabla f(\bar{\mathbf{x}}^t)\|^2] = O\left(\frac{1}{\sqrt{NT}}\right)$$

(Yang-Tang-Lin, ICML'11) : $K = O(T/N)$.
